ABSTRACT: In the present study, an attempt was made to evaluate the changes in testis protein and metabolic enzyme activities induced by epichlorohydrin (ECH), twenty four albino male rats were divided randomly into four groups of six rats each. One group was left untreated as controls, and the other three groups were administered, respectively, for twelve consecutive weeks, (2) 50 mg of ECH /kg/b.wt, (3) 75mg of ECH /kg/b.wt and (4) 100mg of ECH /kg/b.wt. In comparison with the control group, the doses of ECH (75mg/kg/b.wt and 100mg/kg/b.wt) resulted in lower protein levels and higher lactate dehydrogenase (LDH) activities in the testis of male rats than in control rats. The activity of gamma-glutamyl transpeptidase (γ-GT) decreased significantly at the doses of ECH (75mg/kg/b.wt and 100mg/kg/b.wt) group than in the ECH (50mg/kg/b.wt) and control group. However, a significant reduction in the activities of Na⁺/K⁺-, Mg²⁺- and Ca²⁺-ATPases in the (75mg/kg/b.wt and 100mg/kg/b.wt ) ECH treated animals than control rats. Therefore, these changes in testis protein and spermatogenesis-dependent enzymes undoubtedly affect the physiological functions of the testis, which may thereby cause low sperm motility.

INTRODUCTION: Increasing attention to recent trends in declining reproductive health, especially the alarming decrease in male fertility rate worldwide, has led to the 21st century being dubbed the century of reproductive health¹. Epichlorohydrin does not occur naturally in the environment. It is manufactured commercially from chlorine and propylene, or from hydrochloric acid and natural glycerine derived from biodiesel. It is also used in the manufacture of elastomers, glycidil ethers, cross-linked food starch, wet strength resins for the paper industry, water-treatment resins, surfactants, ion-exchange resins, plasticizers, dyestuffs, pharmaceutical products, oil emulsifiers, lubricants and adhesives². Epichlorohydrin is absorbed rapidly via the skin, gastro-intestinal tract, and, in vapour form, via the lungs. It is distributed widely throughout the body. In rats, most absorbed epichlorohydrin is metabolized rapidly, partly to carbon dioxide, which is excreted via the lungs, and partly to urinary metabolites, mainly conjugates². Epichlorohydrin is a bifunctional alkylating epoxide³. It causes delayed erythema, edema,
papules along with burning, and itching when the liquid comes in contact with the skin \(^4\); contact dermatitis has been reported after occupational exposure to epichlorohydrin \(^5\). Epichlorohydrin induced antifertility effects in male rats resembling those induced by alpha-chlorohydrin after a single oral or intraperitoneal dose of 50 mg/kg body weight \(^6\). In male rodents, exposure to epichlorohydrin induced sterility \(^6-^9\).

It is known, for example, that high doses of ECH adversely affect male reproduction function \(^10\). Thus, an investigation not only focusing on the effects of ECH exposure on male reproduction alone, but also measuring their interactive effects on the male reproductive system might prove helpful in determining potential causes of impaired reproductive functions in male rats. Previous investigations have revealed that the ECH causes lower sperm motility in male rats \(^11\), and that ECH affects male reproduction through altering testis mass, cellular morphology and normal spermatogenesis \(^12,13\).

Protein and metabolic enzymes, such as lactate dehydrogenase (LDH) and adenosine triphosphatases (ATPases), are important for the normal function and development of the testis and for sperm motility \(^14-17\). In the present study, we investigated changes in total protein and spermatogenesis-dependent enzymes in testis in order to explore possible pathways of decreased sperm motility and altered levels of serum testosterone induced by ECH \(^18\).

**RESULTS:**

In the present study, an attempt was made to investigate the effect of epichlorohydrin, on testis of adult albino male rats. The protein level was significantly \((p < 0.05 \text{ p} < 0.01)\) decreased in testis after the treatment of epichlorohydrin \((75\text{mg/kg/b.wt} \text{ and } 100\text{mg/kg/b.wt})\) when compared to the control rats. No significant variations were observed in epichlorohydrin \((75\text{mg/kg/b.wt})\) treated groups as compared to control groups (Table 1 and Fig. 1). At the end of ECH \((75\text{mg/kg/b.wt} \text{ and } 100\text{mg/kg/b.wt})\) treatment, the activities \(\gamma\text{-GT}\) activity significantly \((p < 0.05 \text{ p} < 0.01)\) decreased in testis than control rats. But, did not observe any significant changes in the epichlorohydrin \((50\text{mg/kg/b.wt})\) treated patients when compared to control rats (Table 1 and Fig 1).

The significantly \((p < 0.05 \text{ p} < 0.01)\) increased in the LDH activity in testis after epichlorohydrin \((75\text{mg/kg/b.wt} \text{ and } 100\text{mg/kg/b.wt})\) treated rats as compared to control. But, did not observe any significant variations in the epichlorohydrin \((50\text{mg/kg/b.wt})\) treated animals (Table 1 and Fig 1). The data showed significant \((p < 0.05; p < 0.01)\) reduction in testis in the activities of \(\text{Na}^+\text{/K}^+\) -

**MATERIALS AND METHODS:**

**Experimental animals:**

Twelve -week-old adult albino male rats weighing between 150 - 200g, along with supplies of their standard diet, were obtained from animal house centre of “Jawaharlal Nehru Institute of Post Graduate Medical Educations and Research” (JIPMER), Pondicherry.

**Establishment of animal model:**

As in our recent reports \(^11,19\) twenty four of the above male rats were randomly divided into four groups of six rats each: (a) a control group, which was given distilled water and clean air; (b) a ECH group, to which 50 mg /kg/b.wt was administered in their drinking water; (c) a ECH group, to which 75 mg /kg/b.wt was administered in their drinking water and (d) a ECH group, to which 100 mg /kg/b.wt was received in their drinking water. All rats were maintained on standard diets, water \textit{ad libitum} under standard temperature \((22-25\text{°C}), 12/12\text{-hr light/dark cycle, ventilation and hygienic conditions. At the end of weeks, each group was sacrificed for further study.**
ATPases, Ca\textsuperscript{2+}-ATPases and Mg\textsuperscript{2+}-ATPases by epichlorohydrin (50mg/kg/b.wt, 75mg/kg/b.wt and 100mg/kg/b.wt) treatment when compared to control rats (Table 1 and Fig 1).

**DISCUSSION:**

**Effect of ECH on testis protein metabolism of male rats:** Earlier studies have reported that a dose-dependent decrease in protein level in the spermatozoa and reproductive organs of ECH-treated animals \textsuperscript{14, 17, 20-24}. In this study, the total protein levels in the testis of male rats were significantly (P<0.05) decreased in the ECH (75mg/kg/b.wt) group after 12 weeks of ECH treatment when compared to control rats. The mean total protein content over the entire 12-week period was slightly lower in the ECH (50mg/kg b.wt) group, but was drastically (P<0.05) decreased in the ECH (100mg/kg/b.wt) groups. These results clearly suggest that the ECH leads to lower testis protein content than control group.

**Gamma-glutamyl transpeptidase (Gamma-glutamyl transferase, γ-GT),** is the key enzyme in the γ-glutamyl cycle, and plays an important role in the absorption, transport, and synthesis of amino acids.
and proteins. The activity of γ-GT decreased significantly (P<0.05) in ram semen with ingestion of 20 to 200μmol NaF/L has been reported. In the present study, γ-GT activity in the ECH group decreased significantly in the (75mg/kg b.wt) treated group and then dramatically (P<0.05) decreased in the (100mg/kg b.wt) treated group when compared to control rats. Nevertheless, it can be concluded that both protein metabolism and synthesis in testis of male rats is affected by ECH (75mg/kg/b.wt+100mg/kg/b.wt) treated rats, and the influence of ECH on the γ-glutamyl cycle may be responsible for a reduction in testis protein of male rats. The reduction in testis proteins may also be due to interference of ECH with binding of the amino acyl-t-RNA adducts to the ribosomal RNA template, which would then inhibit biosynthesis of protein in testis.

**Effect of ECH on testis metabolic enzyme activities of male rats:**

Lactate dehydrogenase (LDH) and ion-activated adenosine triphosphatases (ATPases) are important for spermatogenesis and testicular metabolism. Many studies have indicated that the activity of these enzymes decreases in testes of ECH-treated animals. In our study, LDH activities increased in the ECH (75mg/kg/b.wt +100mg/kg/b.wt) treated groups for 12 weeks. These results are in accord with those obtained by Zakrzeswsk et al. when they went from lower to higher concentrations of ECH in treating rat sperm samples. Furthermore, the mean values for the entire 12-week period were significantly (P<0.05) increased in the three treatment groups when compared to control rats. These findings indicate that the interaction of ECH can result in higher LDH activity than control animals.

On the other hand, our observations over time show that the activities of Na+/K+- ATPase, Ca²⁺-ATPase and Mg²⁺-ATPase at week 12 in the three treatment groups all decreased significantly (P<0.05) as compared to control rats. It has been reported that the toxic effect of ECH on reproduction is due to the inhibition of many enzymes, particularly those whose cofactor is the cation of a bivalent metal. It is likely, therefore, that some of the deceased enzyme activity found in the present study is the result of damaged testis tissue. However, others have reported that a lower dose ECH can increase enzymes activity by a positive feedback mechanism. Alternatively, the changes in testis metabolic enzyme activities of male rats may be related to both dose and duration of ECH intoxication. Likewise, ECH, which are in vivo metabolic products of alkylating agent/ chlorinated hydrocarbon inhalation, can inhibit or activate activity of certain enzymes by inducing the production of free radicals. In any case, it is evident that with exposure to ECH various types of lesions were likely to result. It should be noted, however, that LDH, which is regarded as a marker of carbohydrate metabolism of germ-cell production and differentiation plays a key role in the process of energy supplementation for spermatozoa motility.

**CONCLUSION:** ATPases, including Na⁺/K⁺-, Ca²⁺-, and Mg²⁺-ATPase, play a key role in exchange of metabolites between Sertoli and developing germ cells and are markers of the metabolic state of germinal epithelium. The changes in these enzymes will undoubtedly affect physiological function in the testis, which may cause significant decline in sperm motility. Nevertheless, the exact alterations in testis physiological function caused by ECH are not clear, and histological and ultra-structural studies are called for in order to illuminate this aspect. In conclusion, both ECH treatments alter testis protein and the activity of some enzymes in male rats, and these changes may be one of the pathways that lead to low sperm motility.
