**ABSTRACT:** *Aerva lanata* has been used in traditional medicine for many years and used for the treatment of urinary bladder and kidney stones. The aim was to study the pharmacognostic characters and antimicrobial activity of important medicinal plant *Aerva lanata* (Amaranthaceae). The physicochemical, phytochemical and fluorescence analysis of powdered aerial and root parts of *Aerva lanata* was performed according to the standardization procedures recommended by the World Health Organization. The physicochemical parameters such as total ash, acid insoluble ash, water-soluble ash reveal that the plant has less amount of carbonates, silicates and are less affected by contamination and inorganic compounds. The various colors obtained by fluorescence were analyzed, and the moisture content of aerial and root parts were found to be 37.5%, 35.33% respectively. The preliminary phytochemical screening showed the presence of alkaloids, saponins, terpenoids, flavonoids, proteins, glycosides, coumarins, carbohydrate, steroids, tannins, phenols and phytosterols. The antimicrobial activity performed of *Aerva lanata* on *Pseudomonas aeruginosa*, *Klebsiella pneumonia*, *Bacillus subtilis*, *Streptococcus mutants*, *Escherichia coli*, *Staphylococcus aureus* showed maximum activity against gram-negative bacteria on aerial parts of *Aerva lanata*. Thus the results of the present study can serve as a valuable source for the identification of this plant and their active components in future investigations.

**INTRODUCTION:** The traditional herbal products are heterogeneous. They impose several challenges like quality control, quality assurance, and regulatory process. Most of the herbal product in the market today has not been subjected to the drug approval process to demonstrate their safety and effectiveness<sup>1</sup>.

The therapeutic efficacy of medicinal plants depends upon the quality and quantity of chemical constituents. The misuse of herbal medicine starts with wrong identification<sup>2</sup>. Pharmacognostic studies of medicinal plants can solve all these problems. Pharmacognostic studies ensure plant identity, lay down standardization parameters which help and prevent adulteration. This ensures reproducible quality of herbal products<sup>3</sup>. Standardization is a system to ensure that every medicine has the correct amount of constituents and will induce its therapeutic effect<sup>4</sup>. Determination of ash residues and active components like saponin, alkaloids play a

significant role in the standardization of the indigenous crude drugs<sup>5</sup>. The extract obtained after standardization may be used as a medicinal agent as such in the form of tinctures or fluid extracts. These medicinal agents contain complex mixtures of many medicinal plant metabolites, such as alkaloids, glycosides, terpenoids, flavonoids<sup>6</sup>.

Antimicrobial screening of plant extracts and phytochemicals represents a starting point for antimicrobial drug discovery<sup>7</sup>. According to Sumitra Chanda, ash values are used to determine the quality and purity of the crude drug. It indicates the presence of various impurities like carbonate, oxalate, and silicate. The water-soluble ash is used to estimate the amount of inorganic compound present in drugs. The insoluble acid ash consists mainly of silica and indicate contamination with earthy material. The moisture content of drugs should be at a minimal level to discourage the growth of bacteria, yeast or fungi during storage. Fluorescence analysis is an important parameter for pharmacognostic evaluation of crude drugs<sup>3</sup>. Thus, the present work was done on *Aerva lanata* which deals with the standardization of medicinal plant; antimicrobial activity has been performed. The objective of the present study was:

- To study the pharmacognostical features of medicinal plant *Aerva lanata*.
- To carry out the phytochemical screening tests to various extracts of *Aerva lanata*.
- To ensure the antibacterial activity of chloroform, methanol aerial and root extracts of *Aerva lanata*.

## MATERIALS AND METHODS:

**Collection of Plants:** The medicinal plant *Aerva lanata* belonging to the family Amaranthaceae has been collected in and around Nagercoil area, Kanya Kumari district, Tamil Nadu during February 2012.

**Identification of Plants:** The collected plants were identified using standard keys, and voucher specimens of these plants were submitted at the herbarium of Scott Christian College (Autonomous), Nagercoil. The voucher number is SCCN 3267.

**Pharmacognostic Standardization Parameters:** The powdered plants chosen for the present study

were subjected to pharmacognostic standardization parameters such as physico-chemical analysis, moisture content, fluorescence analysis, and phytochemical analysis.

**Physico-Chemical Analysis:** The powdered aerial and root parts of *Aerva lanata* were subjected to physicochemical analysis. Total ash, Acid insoluble ash, Water soluble ash, is done based on standard methods.

**i) Determination of Total Ash:** Total ash was determined by weighing 2 gm of air-dried sample in silica dish and incinerated at a temperature not exceeding 450 °C until free from carbon and then was cooled and weighed<sup>8,9</sup>.

$$\text{Total ash \%} = \text{Weight of total ash} / \text{Weight of sample taken} \times 100$$

**ii) Determination of Acid Insoluble Ash:** The total ash was boiled with 25 ml of 2M dilute HCl for five minutes. The insoluble matter was collected on ashless filter paper and was washed with hot water, ignited, cooled in a desiccator and weighed. The percentage of acid insoluble ash was calculated concerning the air-dried sample<sup>10</sup>.

$$\% \text{ Acid insoluble ash value} = \text{Weight of acid insoluble ash} / \text{Weight of sample taken} \times 100$$

**iii) Determination of Water-Soluble Ash:** The total ash was boiled with 25 ml of water for five minutes. The insoluble matter was collected on ashless filter paper and was washed with hot water, ignited for fifteen minutes at a temperature not exceeding 450 °C. The weight of insoluble matter was subtracted from the weight of total ash. The difference in weight represents the water-soluble ash. The percentage of water-soluble ash was calculated concerning the air-dried sample<sup>11,12</sup>.

$$\% \text{ Water soluble ash value} = \text{Weight of water soluble ash} / \text{Weight of sample taken} \times 100$$

**iv) Determination of Moisture Content:** 10g of plant parts were weighed separately in pre-weighed glass Petri dishes and dried in hot air oven (80 -95 °C) for 3 h. The dishes were then transferred to desiccators, cooled to room temperature, and the weight was recorded. The drying was continued until the final weight became stable. The weight differences were noted, and the moisture content was expressed in percentage weight of fresh plant parts<sup>13</sup>.

Moisture content % =  $\frac{\text{Initial weight} - \text{final weight}}{\text{Initial weight}} \times 100$

**Fluorescence Analysis:** The fluorescence analysis of *Aerva lanata* was done by placing powdered aerial and root parts on a slide and observing the color changes under UV and visible lights after treating with several drops of specific reagents such as methanol, hexane, chloroform, ethanol, acetone, acetic acid, propanol, acetonitrile, ethyl acetate, and water. The development of color was noted within 1-2 min to avoid drying and resultant color change<sup>14, 15</sup>.

**Preliminary Phytochemical Screening Tests:** The shade dried parts of aerial and root parts of *Aerva lanata* were extracted in a soxhlet apparatus for 24 h using different solvents in the order of polarity like hexane, chloroform, ethyl acetate, acetone, methanol, water. The extracted solvents were distilled by vacuum distillation under reduced pressure to separate the solvents from the extracts. The crude extracts obtained from soxhlet extraction were subjected to preliminary phytochemical screening. Phytochemical screening involves testing the different extracts of *Aerva lanata* for various phytochemicals by qualitative analysis, which gives a general idea regarding the nature of constituents present in crude extracts<sup>16</sup>. The qualitative phytochemical test carried for various extracts were given below.

**A) Determination of Alkaloids:** About 3 ml of concentrated extract was taken in a test tube, and 1 ml of HCl was added to the mixture and heated gently for 20 min and then cooled and filtered. The filtrate was used for following test

**Wagner's Test:** The filtrate was treated with Wagner's reagent (solution of iodine in potassium iodide); formation of reddish brown precipitate indicates the presence of alkaloid<sup>17</sup>.

**Mayer's Test:** A few ml of filtrate is treated with 4-5 drops of Mayer's reagent (Potassium mercuric iodide) Formation of a yellow or white colored precipitate or turbidity indicates the presence of alkaloids<sup>18</sup>.

#### **B) Test for Saponins:**

**Foam Test:** 5 ml of the extracts were mixed with 20 ml of distilled water then agitated in a graduated

cylinder for about 15 min formation of foam indicates saponin<sup>18</sup>.

**Froth Test:** Exactly 0.5 g of the extract was dissolved in distilled water in a test tube. Frothing which persisted on warming was taken as preliminary evidence for saponins<sup>19</sup>.

#### **C) Test for Phytosterols:**

**Libermann Burchard's Test:** Extracts were treated with chloroform and filtered. The filtrates were treated with a few drops of acetic anhydride, boiled and cooled. Concentrated sulphuric acid was added. The formation of a brown ring at the junction indicates the presence of phytosterols<sup>20</sup>.

#### **D) Test for Proteins:**

**Xanthoproteic Test:** The extracts were treated with a few drops of concentrated nitric acid. Formation of yellow color indicates the presence of proteins<sup>21</sup>.

#### **E) Test for Triterpenes:**

**Salkowski Test:** Extracts were treated with a few drops of concentrated sulphuric acid were added to the chloroform solution, shaken and allowed to stand, the appearance of golden yellow color indicates the presence of triterpenes<sup>21</sup>.

#### **F) Test for Diterpenes:**

**Copper Acetate Test:** The extract was dissolved in water and treated with 10 drops of copper acetate solution; the formation of emerald green color indicates the presence of diterpenes<sup>19</sup>.

#### **G) Test for Glycosides:**

**Glycoside Test:** 0.5 mg of the extract was dissolved in 1 ml of water, and then the aqueous NaOH solution was added. Formation of yellow color indicates the presence of glycosides<sup>22</sup>.

**Concentrate H<sub>2</sub>SO<sub>4</sub> Test:** To 5 ml extract, add 2 ml glacial acetic acid, one drop 5% FeCl<sub>3</sub> and concentrated H<sub>2</sub>SO<sub>4</sub>. Brown ring appears indicates the presence of glycosides<sup>23</sup>.

#### **H) Test for Tannins:**

**Ferric Chloride Test:** To the extracts add a few drops of 1% neutral ferric chloride solution were added, the formation of a blackish blue color indicates the presence of tannins<sup>21</sup>.

**I) Test for Steroids:**

**Salkowski's Test:** 5 ml of the extract was dissolved in 2 ml of chloroform, and an equal volume of concentrated sulphuric acid was added along the sides of the test tube. The upper layer turns red, and the lower layer turns yellow with green fluorescence, indicating the presence of the steroids <sup>24</sup>.

**J) Test for Flavonoids:**

**NaOH Tests:** To 2-3 ml extract, few drops of sodium hydroxide were added in a test tube. Formation of intense yellow color that becomes colorless on the addition of a few drops dilutes HCl indicates the presence of flavonoids <sup>25</sup>.

**Pew's Tests:** To 2-3 ml extract, zinc powder was added in a test tube, followed by dropwise addition of concentrated HCl. Formation of purple-red or cherry color indicates the presence of flavonoids <sup>26</sup>.

**K) Test for Coumarins:** 10% NaOH (1 ml) was added to 1 ml of the plant extracts, the formation of yellow color indicated the presence of coumarins <sup>27</sup>.

**L) Test for Carbohydrates:**

**Molisch Test:** To 2–3 ml of the aqueous extract, add two drops of alpha-naphthol solution in alcohol shake and add concentrated sulphuric acid from the sides of the test tube. Violet ring is formed which indicate the presence of carbohydrates <sup>16</sup>.

**Antimicrobial Activity of Medicinal Plants:** The chloroform and methanol extracts of aerial and root parts of *Aerva lanata* were chosen for the antimicrobial studies. Antibiotic susceptibility tests were determined by the agar disc diffusion (Kirby–Bauer) method. Bacterial strains were swabbed using sterile cotton swabs in the nutrient agar plate. A disc of 6 mm was punched from Whatman no.1 filter paper. Up to 10 µl of each concentration of the extract were respectively introduced in the discs using sterile pipettes.

The disc was then placed on the surface of the medium, and the compound was allowed to diffuse for 5 min, and the plates were kept in incubation at 37 °C for 24 hours. At the end of incubation, inhibition zones were examined around the disc and measured with a transparent ruler in millimeters <sup>28</sup>.

**RESULTS AND DISCUSSION:**

**Physico-Chemical Evaluation:** Physico-chemical parameters of a crude powder of *Aerva lanata* were shown in **Table 1**.

**TABLE 1: PHYSICO - CHEMICAL PARAMETERS OF CRUDE POWDER OF AERVA LANATA**

S. no	Name of the physico-chemical constants	<i>A. lanata</i> (% of the composition) aerial	<i>A. lanata</i> (% of composition) root
1	Moisture content	37.5	35.33
2	Total ash	9.5	9.65
3	Acid-insoluble ash	4.45	5.55
4	Water soluble ash	3.8	4.95

The physicochemical parameter values of aerial and root parts of *Aerva lanata* reveals that the moisture content of *Aerva lanata* aerial and root parts was found to be 37.5% and 35.33% respectively. Thus, there is a less possibility of microbial growth, fungi, and contamination. The total ash value of aerial and root parts of *Aerva lanata* is found to be 9.5% and 9.65%. The total ash of the crude powders is not too high. So the plant may contain the appropriate amount of physiological and non-physiological ash. The acid insoluble ash value of aerial and root parts of *Aerva lanata* is found to be 4.45% and 5.55% respectively. The values of acid insoluble ash show that there is less possibility for each plant to be contaminated with silica materials. The water-soluble ash value of aerial and root parts of *Aerva lanata* was found to be 3.8% and 4.95%, which indicates that the constituents present in root parts of *Aerva lanata* were more extracted by water than root parts.

**TABLE 2: FLUORESCENCE ANALYSIS OF AERIAL PARTS OF AERVA LANATA**

Treatment	U.V light	Visible light
Powder as such	Green	Pale yellow
Powder + methanol	Green	Light green
Powder + hexane	Light green	Light green
Powder + chloroform	Black	Violet
Powder + ethanol	Green	Light green
Powder + acetone	Green	Pale green
Powder + acetic acid	Pale green	Pale green
Powder + propanol	Dark green	Violet
Powder + acetonitrile	Green	Pale violet
Powder + ethyl acetate	Green	Green
Powder + water	Green	Yellow-green

**Fluorescence Analysis:** The powdered aerial and root parts of *Aerva lanata* were subjected to fluorescence analysis. The results of fluorescence analysis of *Aerva lanata* were expressed in **Table 2** and **Table 3**.

**TABLE 3: FLUORESCENCE ANALYSIS OF ROOT PARTS OF AERVA LANATA**

Treatment	U.V light	Visible light
Powder as such	Grey	Grey
Powder + methanol	Green	Grey
Powder + hexane	Green	Grey
Powder + chloroform	Blue	Grey
Powder + ethanol	Green	Violet
Powder + acetone	Dark green	Grey
Powder + acetic acid	Dark green	Violet
Powder + propanol	Blue	Violet
Powder + acetonitrile	Dark brown	Grey
Powder + ethyl acetate	Brown green	Brown
Powder + water	Blue	Brown

The powdered aerial parts of *Aerva lanata* as such, and on treatment with methanol, hexane, ethanol, acetone, acetic acid, propanol, acetonitrile, ethyl acetate and water exhibit green colour in U.V light which may be due to the presence of compounds such as furanocoumarins, phytosterols, steroids, alkaloids, polar compounds in the crude powder<sup>29-33</sup>. The aerial parts treated with methanol, hexane, ethanol, acetone, acetic acid and ethyl acetate in visible light shows green color this may be due to saponins, terpenoids in the crude powder<sup>31,34</sup>.

The violet color obtained on treatment with chloroform, propanol, and acetonitrile in visible light is due to saponins, sterols<sup>34,35</sup> present in the sample. The crude powder with chloroform in the presence of U.V light fluoresces black which may be due to the flavonoids present in the powder<sup>36</sup>. The crude powder as such shows pales yellow color in visible light which indicates the presence of flavonoid compounds in the samples. The powder with water shows yellow-green color under visible light may be due to the presence of 'chlorophyllide b' compound present in sample<sup>36</sup>.

The powdered root parts of *Aerva lanata* as such grey in color in U.V light, this may be due the presence of flavonoids in sample<sup>37</sup> and grey color obtained in visible light on treatment with methanol, hexane, chloroform, acetone, acetonitrile is due to the presence of 'pheophytin a' present in

the sample<sup>36</sup>. The powder when treated with methanol, hexane, ethanol, acetone, acetic acid under U.V light shows green color which may be due to the presence of furanocoumarins, phytosterols, steroids, alkaloids, polar compounds in the crude powder<sup>29-33</sup>. The powder treated with acetonitrile exhibit brown color under U.V light may be due to polyphenols, flavonoids in sample<sup>38,33</sup>. The powder with ethyl acetate in U.V light shows brown-green color which may be due to the presence of most flavones, glycosides, bioflavonoids and unusually substituted flavones<sup>36</sup>.

The powder shows blue color in U.V light when treated with chloroform, propanol, water which may be due to the presence of flavonoids in sample<sup>34</sup>. The crude powder as such, on treatment with methanol, hexane, chloroform, acetone, acetonitrile in visible light shows grey color this may be due to 'pheophytin a' present in sample<sup>36</sup>. Violet color was obtained when the powdered samples were treated with ethanol, acetic acid, propanol under visible light may be due to saponins, steroids present in sample<sup>34,35</sup>. The brown color obtained on treatment with ethyl acetate and water in visible light indicates the presence of glycosides<sup>39</sup>.

Qualitative phytochemical screening was done in various aerial extracts of *Aerva lanata* are presented in **Table 4** showed the presence of alkaloids, saponins, phytosterols, triterpenes, proteins, glycosides, coumarins, flavonoids. Saponin is found in only in chloroform extract. Coumarin, Protein, Glycosides were found almost in all extracts. The maximum numbers of phytochemical constituents are found in chloroform, ethyl acetate, and water extract. The minimum number of phytochemical constituents is found in acetone extract.

Qualitative phytochemical screening was done in various root extracts of *Aerva lanata* are presented in the **Table 5** showed the presence of alkaloids, saponins, phenols, coumarins, steroids, proteins, triterpenes, glycosides, flavonoids, carbohydrates, tannins and phytosterols. The phytochemical coumarin is observed only in the acetone extract. The carbohydrates and tannins are found in methanol and water extracts. Glycosides were found in all the extracts and proteins were found in all extracts except hexane. The maximum amount

of phytochemical constituents is found in methanol extract, and the minimum number of phyto-chemical constituents is found in hexane and ethyl acetate extracts.

**TABLE 6: ANTIMICROBIAL ACTIVITY OF CHLOROFORM EXTRACTS OF AERVA**

Organism	C <sub>2</sub>	C <sub>3</sub>	Positive Amikacin	Negative
<i>Escherichia coli</i>	NZ	NZ	20 mm	-
<i>Staphylococcus aureus</i>	9 mm	9 mm	20 mm	-
<i>Bacillus subtilis</i>	10 mm	0 mm	20 mm	-
<i>Pseudomonas aeruginosa</i>	11 mm	0 mm	22 mm	-
<i>Klebsiella pneumoniae</i>	11 mm	0 mm	22 mm	-
<i>Streptococcus mutants</i>	10 mm	10 mm	20 mm	-

NZ = No Zone of inhibition, C<sub>1</sub>= Chloroform extract of *Dichrostachys cinerea* leaves, C<sub>2</sub>, C<sub>3</sub>= Chloroform aerial and root extracts of *Aerva lanata*.

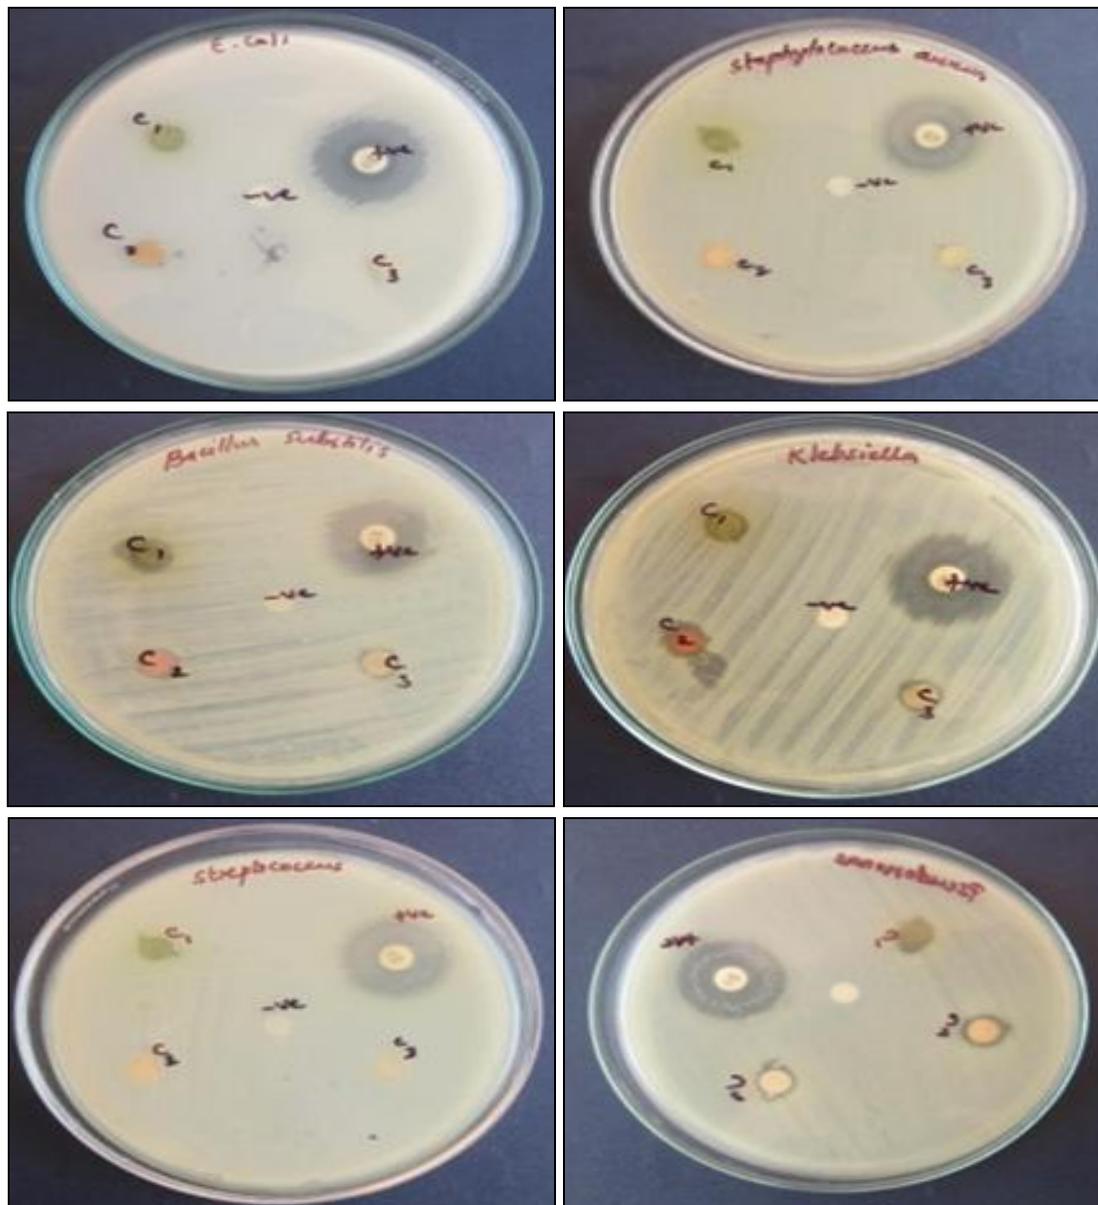

**Antimicrobial Activity of Chloroform Extracts of *Aerva lanata*:** The chloroform extract parts of *Aerva lanata* showed no inhibitory effect against *Escherichia coli*. In chloroform aerial extracts of *Aerva lanata* the maximum inhibitory effect was observed against *Pseudomonas aeruginosa* (11 mm), *Klebsiella pneumonia* (11 mm). The

moderate activity was observed against *Bacillus subtilis* and *Streptococcus mutants* (10 mm) and *Escherichia coli* (9 mm).

In chloroform root extracts of *Aerva lanata*, the maximum zone of inhibitory activity was found against *Bacillus subtilis*, *Pseudomonas*

*aeruginosa*, *Klebsiella pneumonia* and *Streptococcus mutants* (10 mm) and moderate inhibitory activity were found in *Staphylococcus aureus* (9mm). From the above observation, the maximum inhibitory activity was found in chloroform aerial extracts of *Aerva lanata* against

*Pseudomonas aeruginosa*, *Klebsiella pneumonia* than other extracts. Thus, comparing the antimicrobial activity of gram positive and gram negative bacteria, the maximum inhibitory activity was found against gram-negative bacteria than gram-positive bacteria.

**FIG. 1: SHOWING THE ANTIMICROBIAL ACTIVITY OF CHLOROFORM EXTRACTS OF AERVA LANATA.** C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub> - represents the antimicrobial activity of chloroform extracts of *Dichrostyachys cinerea* leaves, aerial and root parts of *Aerva lanata*

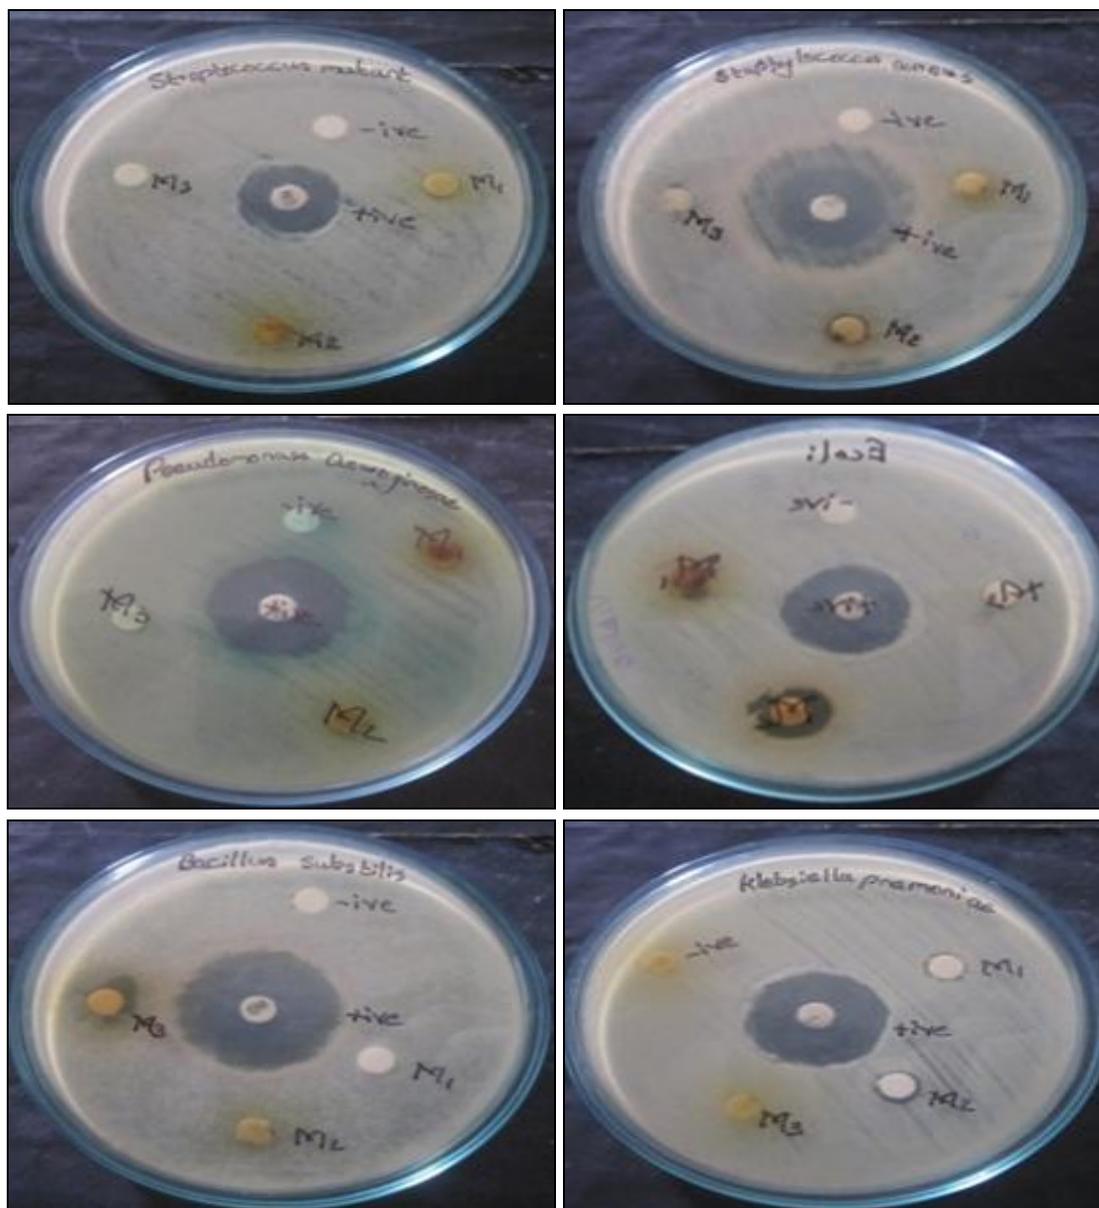

**Antimicrobial Activity of Methanol Extracts of *Aerva lanata*:** The methanol aerial extracts of *Aerva lanata* showed maximum inhibitory activity (15mm) against *Escherichia coli* whereas moderate antimicrobial activity was observed against *Staphylococcus aureus* and *Klebsiella pneumonia* (10mm), but the antimicrobial activity was not observed against *Bacillus subtilis*, *Pseudomonas*

*aeruginosa*, and *Streptococcus mutants*. In methanol root extracts of *Aerva lanata* the maximum zone of inhibition was obtained against *Bacillus subtilis* (10 mm) whereas moderate zone of inhibition is observed against *Escheria coli*, *Pseudomonas aeruginosa* and *Streptococcus mutants* (8 mm) but the antimicrobial activity was not observed against *S. aureus* and *K. pneumonia*.

**TABLE 7: ANTIMICROBIAL ACTIVITY OF METHANOL EXTRACTS OF AERVA LANATA**

Organism	M <sub>2</sub>	M <sub>3</sub>	Positive Chloramphenicol	Negative
<i>Escherichia coli</i>	15 mm	8 mm	20 mm	-
<i>Staphylococcus aureus</i>	10 mm	NZ	30 mm	-
<i>Bacillus subtilis</i>	NZ	10 mm	30 mm	-
<i>Pseudomonas aeruginosa</i>	NZ	8 mm	25 mm	-
<i>Klebsiella pneumoniae</i>	10 mm	NZ	25 mm	-
<i>Streptococcus mutants</i>	NZ	8 mm	18 mm	-

NZ= No Zone of inhibition, the M<sub>1</sub>= Methanol extract of *Dichrostachys cinerea* leaves, M<sub>2</sub>, M<sub>3</sub>= Methanol extracts of aerial and root parts of *Aerva lanata*

**FIG. 2: SHOWING THE ANTIMICROBIAL ACTIVITY OF METHANOL EXTRACTS OF AERVA LANATA.** M<sub>1</sub>, M<sub>2</sub>, M<sub>3</sub> - represents the antimicrobial activity of methanol extracts of *Dichrostachys cinerea* leaves aerial and root parts of *Aerva lanata*.

When we compare the results of antimicrobial activity of chloroform and methanol extracts the maximum amount of antimicrobial activity was obtained from the aerial extracts of *Aerva lanata* against gram-negative bacteria.

**CONCLUSION:** Standardization is an essential measure for quality, purity and sample identification. Evaluation of extractive values is helpful in the estimation of specific constituents soluble in a particular solvent.

Physicochemical and chemical analysis confirms the quality and purity of the plant and its identification. Physicochemical parameters like moisture content of the selected plants are found to not high, and there be a less possibility of microbial attack. Total ash of the plants was found to be less, so the plants have less amount of carbonates, silicates, *etc.* Acid-insoluble ash, water-soluble ash values are less; this reveals that the plants are very less affected by contamination and inorganic compounds. Phytochemical analysis showed the presence of active phytoconstituents present in the extracts of each plant taken for the study. The antimicrobial activity is found mostly in gram-negative bacteria.

From the above results, the physicochemical parameters will help an individual, whether the plant material is undergone adulteration or not. Phytochemical analysis of the plant is very important commercially and has greatly involved in pharmaceutical companies for the production of new drugs for curing various diseases. The preliminary phytochemical screening reveals the useful findings of the chemical constituents present in the plants. The Thin Layer Chromatography performed on various extracts showed the presence phytochemicals present in the plants. From the antimicrobial study, medicinal plants can be used as antimicrobial agents in new drugs for therapy of infectious diseases in human. Here, the information collected was useful for further pharmacological and therapeutical evaluation along with the standardization of plant material.

**ACKNOWLEDGEMENT:** The authors are thankful to the authorities of Scott Christian College (autonomous), Nagercoil, for granting permission to do the work.
